• Small populations workstream is part of DIA Adaptive Design Scientific Working Group (ADSWG), a group of 180 statisticians and clinicians from industry, academia, and national health authorities (FDA and EMEA)
Small Populations Within A Common Disease

- The increasing discovery of molecular subtypes of cancer leads to small subgroups that actually correspond to orphan or “niche” indications, even within larger tumor types.
- Enrolling enough patients for confirmatory trials in these indications may be challenging.
- The shift to a molecular view of cancer requires a corresponding paradigm shift in drug development approaches.
- Exclusive use of “one indication at a time” approaches will not be sustainable.
Approaches to development based on predictive biomarkers

- Optimized co-development of a single drug and its companion diagnostic
  - Gives a clear hypothesis and answer and still has a role in selected instances
  - Will be challenging to do in niche indications

- “Umbrella” trials
  - One tumor type with multiple drugs and predictive biomarkers
  - Patients are matched to drugs based on predictive biomarkers
  - Cooperation among multiple sponsors
  - Examples: BATTLE, I-SPY, Lung-MAP

- “Basket” or “bucket” trials
  - Multiple tumor types with one drug and predictive biomarker
  - Approval based on pooled analysis
  - Premise is that molecular subtype is more fundamental than histology
  - Single sponsor

186 patients with 40 different malignancies with known genomic mechanisms of activation of imatinib target kinases

Kit, PDGFRA or PDGFRB

Imatinib 400-800 mg BID primary Endpoint ORR

Synovial Sarcoma
Aggressive Fibromatosis
Dermatofibrosarcoma Protuberans
Aggressive Systemic mastocytosis
Hyper-eosinophilic syndrome
Myelo-proliferative disorder

1/16 (6%) 2/20 (10%) 10/12 (83%) 1/5 (20%) 6/14 (43%) 4/7 (58%)

Lead to supplemental indications for these 4 subsets after pooling with other trials and case reports

13 centers in consortium: North America, Europe, Australia

Blumenthal. Innovative trial designs to accelerate the availability of highly effective anti-cancer therapies: an FDA perspective, AACR 2014
Basket Trials to Date

• A similar design to Imatinib B2225 was endorsed at a Brookings/Friends Conference in 2011
• Common features:
  – Exploratory and opportunistic in nature
  – Single-arm trials with ORR as primary endpoint
  – Intend to use pooled population for primary analysis to gain broader indication across tumor types (individual tumor type is not adequately powered)
  – Involve possibly transformative medicines in patients with great unmet need and seemingly exceptionally strong scientific rationale
Issues

• Clinical data to support pooling my be limited, and treatment effect may differ between tumor types
  – Vemurafenib works in melanoma with BRAF V600E mutation but not colorectal cancer with same mutation
• Not all drugs hoped to be transformational live up to this promise
• Response rate may not predict overall survival
• Single arm trials are subject to patient selection bias
• Predictive effect of a biomarker is confounded with the prognostic value which is often unknown
• Health authorities can be non-committal upfront
DIA Small Population Pathway Subteam

• Can we develop a generalizable confirmatory basket design concept with statistical rigor?
  – Applicable not only to exceptional cases, but to all effective medicines in any line of therapy
  – Follow existing accelerated and standard approval pathways to increase drug approvability

• This would have multiple benefits
  – Increase and accelerate access to effective medicines for patients in niche indications
  – Provide sponsors with cost-effective options for development in niche indications
  – Provide health authorities with more robust packages for evaluation of benefit and risk
GENERAL DESIGN CONCEPT
SELECTION

PRUNING (External Data)

PRUNING (Interim endpoints)

Consistent trend in definitive endpoint

FULL APPROVAL (Pooled analysis of definitive endpoint)

Accelerated Approval Option

October 25, 2017
Features of the Design (I)

- Tumor histologies are grouped together, each with their own control group (shared control group if common SOC)
- Randomized control is preferred
  - Single arm cohorts with registry controls may be permitted in exceptional circumstances as illustrated by imatinib B225 and others
- In an example of particular interest, each indication cohort is sized for accelerated approval based on a surrogate endpoint such as progression free survival (PFS)
  - This may typically be 25-30% of the size of a Phase 3 study
- Initial indications are carefully selected as one bad indication can spoil the entire pooled result
Features of the Design (II)

- Indications are further “pruned” if unlikely to succeed, based on:
  - External data (maturing definitive endpoint from Phase 2; other data from class)
  - Internal data on surrogate endpoint
- Sample size of remaining indications may be adjusted based on pruning
- Type I error threshold will be adjusted to control type I error (false positive rate) in the face of pruning
  - Pruning based on external data does not incur a statistical penalty
  - Discussed in more detail later in talk
- Study is positive if pooled analysis of remaining indications is positive for the primary definitive endpoint
  - Remaining indications are eligible for full approval in the event of a positive study
  - Some of the remaining indications may not be approved if they do not show a trend for positive risk benefit as judged by definitive endpoint
CHALLENGES OF BASKET DESIGNS AND RECOMMENDATIONS FOR OVERCOMING THEM
Challenge 1: Risks of Pooling

- One of more bad indications can lead to a failed study for all indications in a basket
- Histology can affect the validity of a molecular predictive hypothesis, in ways which cannot always be predicted in advance
  - Vemurafenib is effective for BRAF 600E mutant melanoma, but not for analogous colorectal cancer (CRC) tumors
  - This was not predicted in advance but subsequently feedback loops leading to resistance were characterized
Basket trials are recommended primarily after there has been a lead indication approved (by optimized conventional methods) which has validated the drug, the predictive biomarker hypothesis, and the companion diagnostic

– Example, melanoma was lead indication preceding Brookings trial proposal in V600E mutant tumors

Indications should be carefully selected

Indications should be pruned in several steps before pooling
Challenge 2: Adjusting for Pruning

- Pruning indications that are doing poorly on surrogate endpoints may be seen as cherry picking
  - This can inflate the false positive rate, an effect termed “random high bias”

- Addressing the challenge:
  - Emphasize use of **external data**, especially maturing Phase 2 studies, for pruning
    - Pruning with external data does not incur a penalty for random high bias
  - Apply statistical penalty for control of type I error when applying pruning using **internal data**
    - Methods for calculating the penalty are described in stat methods papers (see key references)
    - Rules for applying penalty must be prospective
    - Penalty is not large enough to offset advantages of design
Challenge 3: Will the companion diagnostic assay generalize across indications?

- Analytical properties of assay may depend on tissue type
- Cutoff between biomarker positive and negative may vary between tissue types for a continuous biomarker

Addressing the challenge:
- Analytical validation of the assay for all relevant indications prior to study start
- Prior to study start, recommend biomarker stratified randomized phase 2 studies to set provisional cutoffs for continuous biomarkers in each indication to the extent feasible
Challenge 4: Availability of tissue

- Tissue sampling and processing are variables that can greatly affect the outcome of a study based on a predictive biomarker

- Basket studies will require cooperation and uniformity across departments organized by histology

- Addressing the challenge:
  - The sponsor must have extensive contact with the pathology department and relevant clinical departments at all investigative sites and provide standard methods for tissue sampling, handling, and processing
  - The sponsor should engage an expert pathologist who is dedicated to training prior to trial start, and troubleshooting during the trial
Challenge 5: Clinical validity of the predictive biomarker hypothesis

The clinical validity of the predictive biomarker can only be verified by inclusion of “biomarker negative” patients in the confirmatory study.

Addressing the challenge

– Recommend a smaller pooled, stratified cohort for biomarker negative patients, powered on surrogate endpoint
  • Would need to expand the biomarker negative cohort (to evaluate definitive endpoint) if surrogate endpoint shows possible benefit

– Prior evidence should permit this if:
  • An approved lead indication has already provided clinical evidence for the predictive biomarker hypothesis
  • Prior phase 2 studies support the predictive biomarker hypothesis in other indications
Challenge 6: High Screen Failure Rate

- **Pro:** patients will have access to tailored therapy

- **Con:** patient has a high risk of being a screen failure if biomarker positive subgroup is low prevalence

- **Addressing the challenge:**
  - Study should provide a broad-based test like NGS which will give the patient some guidance on alternative therapies if they are screen failures for basket study
Challenge 7: Interim endpoints may not predict definitive endpoints

Addressing the challenge:

– Prefilter indications based on maturing definitive endpoint data from phase 2
  • See Figure 2
– Require consistent trend in definitive endpoint for final full approval
Phase 2 Influencing Phase 3 Adaptation: The Phase 2+ Method

October 25, 2017
Another Possible Source of External Data

- Real World Data (RWD) from Off-Label Use
- Impact of RWD on basket trial performance is currently under study in a project led by postdoctoral fellow Daphne Guinn

October 25, 2017
Designs to Be Compared

- Sample size changes after pruning
  - D0: No pruning and no change (benchmark)
  - D1: No increase to sample size after pruning
  - D2: Sample size in pooled analysis after pruning remains same as planned for the trial (SS)
  - D3: Sample size for trial remains same after pruning as planned for the trial (SS)

Type I error control

- $k$ tumor indications each with sample size of $N$ and all with 1:1 randomization
- An interim analysis is conducted at information fraction $t$ for each tumor indication and a tumor will not be included in the pooled analysis if $p$-value $> \alpha_t$
- The pooled analysis will be conducted at $\alpha^*$ so that the overall Type I error is controlled at $\alpha$ when there is no treatment effect for any tumor ($H_0$)
- What is $\alpha^*$?
Solving for adjusted alpha ($\alpha^*$)

- Let $Y_{i1}$ be the test statistics based on information fraction $t$, and $Y_{i2}$ be the test statistics based on the final analysis of data in the $i$-th cohort ($i=1, 2,...,k$)
- Suppose that $m$ cohorts are included in the final analysis ($m\geq1$), and let $V_m$ be the corresponding test statistics. The probability of a positive outcome in pooled analysis is
  \[ Q_0(\alpha^*|\alpha_t, m) = \Pr_{H_0}(\cap\{Y_{i1} > Z_{1-\alpha_i} \text{ for } i=1,...,m\}, \cap\{Y_{j1} < Z_{1-\alpha_i} \text{ for } j=m+1,...,k\}, V_m > Z_{1-\alpha^*}) \]
  or
  \[ Q_0(\alpha^*|\alpha_t, m) = \Pr_{H_0}(\cap\{Y_{i1} > Z_{1-\alpha_i} \text{ for } i=1,...,m\}, V_m > Z_{1-\alpha^*})(1 - \alpha_t)^{(k-m)} \]
- $\alpha^*$ is solved from below where $c(k, m) = k!/((k-m)!m!)$
  \[ \sum_{m=1}^{k} c(k, m)Q_0(\alpha^*| \alpha_t, m) = \alpha \]
$\alpha^*$ decreases with increasing $k$ as expected, but its relationship with $\alpha_t$ is complicated with the interplay between cherry-picking and futility stopping.
Strong control of Type I error

• This problem is still open
• Challenge: one or more strongly positive indications can drive an overall pooled positive result and negative indications are carried along
• Considerations:
  – Should a basket trial for 5 indications have lower type I error than those 5 indications studied individually (i.e. 0.05 two-sided \( \times 5 \))?
  – Is this different from a conventional phase 3 trial in a broad population? A positive result in such a trial is often driven by a subgroup, known or unknown
• Simulation of type I error under specific cases is planned in my group

October 25, 2017
Comparison of operating characteristics

• k=6 tumor indications with total planned event size (kn) ranging from 150-350
  – The true treatment effect is $-\log(0.6)$, or hazard ratio of 0.6 in a time-to-event trial

• Pruning occurs at when half of the events have occurred

• Number of active indications (g) with target effect size ranges from 3 to 6, with remaining ones inactive

An Application of Special Interest

- A randomized controlled basket trial with 1:1 randomization in 6 tumor indications, each targeting a hazard ratio of 0.5 in PFS with 90% power at 2.5% alpha
  - 88 PFS events and 110 patients planned for each indication
  - PFS analysis is conducted when all are enrolled
- D2 is applied to keep total sample size at 660 in pooled population targeting 430 death events
  - The study has ~90% power to detect a hazard ratio of 0.7 in OS at 0.8% alpha (after taking the penalty) assuming \( \rho = 0.5 \)
  - Observed hazard ratio ~0.79 or lower for a positive trial in pooled population (vs ~0.84 under D0)
- Potential to gain approvals in 6 indications based on comparable sample size to a conventional Phase 3 trial
Conclusions

- It is feasible to create a general design concept for a basket study that is suitable for many agents.
- Multiple challenges can be addressed with careful planning.
- Benefits include:
  - Increased and earlier patient access to targeted therapies for small subgroups.
  - Cost-effective methods for sponsors to develop targeted agents in small subgroups.
  - More robust datasets for health authorities to assess benefit-risk in these small patient groups.
